Clinical Practice Guidelines
for Depression in Adults in the Primary Care Setting

Disease Criteria
Major Depression
The essential feature of a Major Depressive episode is a period of at least 2 weeks during which there is depressed mood or the loss of interest or pleasure in nearly all activities.

Five (or more) of the following symptoms have been present during the same 2-week period and represent a change from previous functioning; at least one of the symptoms is either depressed mood or loss of interest or pleasure.

- Depressed mood
- Loss of interest or pleasure in nearly all activities
- Thoughts of death/suicidal
- Weight loss/gain
- Fatigue/loss of energy
- Insomnia/hypersomnia
- Psychomotor retardation/agitation
- Worthlessness/guilt
- Impaired concentration

Dysthymia
This is a depression of less severity than Major Depression that usually begins in childhood and adolescence, and must be present for at least 2 consecutive years without a period of greater than 2 months of absence of symptoms.

Depressive Disorder Not Otherwise Specified (NOS)
This is a depression that does not strictly meet the severity or duration criteria of the other diagnoses.

Screening
A patient self-reported questionnaire is recommended (refer to Appendices 1 & 2 for examples of patient screening tools and Appendix 3 for patient questionnaire scoring guidelines). Screening may be completed by the patient during the office visit.

Screening is recommended for:
- All new patients
- Existing patients (at least annually)
- High-risk patients (e.g., stroke, dementia, diabetes, coronary artery disease, chronic pain)

Suicidality Assessment
An essential part of the initial evaluation of clinical depression is assessing suicide potential. The evaluation should include:

- Assessment of suicide risk factors: hopelessness, general medical illnesses, family history of substance use and/or suicide, psychotic symptoms, living alone with little social support, prior suicide attempts.
- Direct inquiry about the content and frequency of suicidal ideation, intent, and plans.
- Factors that argue against the patient making an attempt.
- Patient’s access to means of suicide and lethality of those means.

If the evaluation reveals any significant degree of suicidal risk, then an immediate call should be made to the mental health provider for psychiatric assessment at the appropriate level of care.
Goals of Treatment

- Reduce if not remove all symptoms of the disease.
- Restore occupational and psychosocial functioning.
- Reduce the likelihood of relapse and recurrence.

Types and Evaluation of Treatment

- Psychotherapy - Patients with mild to moderate clinical depression (usually Dysthymia or Depressive Disorder NOS) may be selected for psychotherapy alone, if the patient prefers. If symptoms do not significantly improve within 2 to 3 months, then medication should be strongly considered.
- Medication - Patients with moderate to severe clinical depression (usually Major Depression) are appropriately selected for medication, whether or not formal psychotherapy is also used.
- Medication and Psychotherapy - This combination may hold a particular advantage for complicated, chronic depressions. It may also be advantageous for patients with only a partial response to either treatment alone.
- ECT - This is a first-line treatment option for only certain patients. It is recommended that this option be selected only after psychiatric consultation.

Initial Medication Selection and Management

- An antidepressant medication is recommended as an initial treatment in individuals with mild-moderate major depressive disorder.
- Since the effectiveness of different antidepressants are comparable in nature, initial selection of a specific agent should be based on anticipated side effects and safety or tolerability. Generally, a selective serotonin reuptake inhibitor (SSRI) would usually be the first choice unless the patient has a history or risk of intolerable side effects, is taking other essential medications that put the patient at risk for significant drug interactions, or has a personal or family history of a positive response to another class of antidepressants. Some authorities recommend lower starting doses for women.
- Starting dosages may have to be reduced to lessen side effects and improve compliance. It is highly recommended in the elderly to reduce these starting dosages by half.

Note: Specific Member benefit coverage formulary can be found at www.carefirst.com/rx.

Office Visit Frequency

- Frequent office visits with the prescribing physician during the first 4-12 weeks of treatment are usually necessary to assess efficacy and side effects, as well as make any medication adjustments to optimize response.
- A first follow-up visit is recommended within 1 to 4 weeks after the initial prescription. At follow-up visits re-assess the diagnosis of depression and measure changes in symptom severity (depression scores) and patient function. (Refer to Appendix 5 for an example of a depression monitoring tool).
- The patient should be seen at least 3 times in the critical 12 weeks acute treatment phase.
- If treating a patient in concert with a behavioral health therapist conducting psychotherapy, at least one of these 3 follow-up visits need to be with the PCP. At this time, advise the patient to call the PCP between visits for any side effects or problems.
- Continue to monitor for safety.

Secondary Adjustment Strategies

- Early signs of positive response can occasionally be seen after one week, but usually 4 to 6 weeks is required for a full response.
- Adequate treatment for 6 to 8 weeks is necessary before concluding that a patient is not responsive to a particular medication.
- If side effects are tolerable, then titration of the dosage upward is a first adjustment strategy to consider.
- Occasionally, titration of the dosage downward is a first adjustment strategy if it is concluded that the depressive symptoms are responding but side effects are interfering.
- Either of these strategies can certainly be followed during the first 6 to 8 weeks if judged as useful to increase response.
If a patient is deemed unresponsive to a particular SSRI or has intolerable side effects, then a trial of a different SSRI often yields positive results.

Other medication alternatives include selecting an antidepressant from a different class, combining antidepressants, or adding augmentation medications such as stimulants, lithium, or thyroid hormone. Combining antidepressants and adding augmentation medications are best managed by a psychiatrist.

Antidepressant Side Effects

Side effects account for as many as two-thirds of all pre-mature discontinuations of antidepressants. Most side effects are early onset and time limited and include decreased appetite, nausea, diarrhea, agitation, anxiety, and headache. These side effects can be managed by temporary aids to tolerance. Persistent or late onset side effects, which may include apathy, fatigue, weight gain, and sexual dysfunction, may require additional medications or a switch in antidepressants. Strategies for managing antidepressant side effects include:

- Allow the patient to verbalize his/her complaint about side effects.
- Wait and provide support. Some side effects will subside over 1 to 2 weeks.
- Lower the dose temporarily.
- Treat the side effects. (Refer to Appendix 4)
- Change to a different antidepressant.
- Discontinue medications and start psychological counseling.

Continuation of Treatment

- If this is an episode of clinical depression in a patient with a good premorbid mood history and without significant family history of depression, then effective medication should be continued for at least 12 months before considering discontinuation.
- Generally, medications should be discontinued through a gradual taper to avoid any uncomfortable physical withdrawal.
- If this is a chronic or recurrent clinical depression, "double depression" (Major Depressive episode in a patient with Dysthymia), or depression in a patient with a positive family history, then indefinite maintenance on effective antidepressant medication should be considered.
- Risk factors for recurrence of Major Depressive Disorder (MDD) include a prior episode of MDD, Dysthymia, additional psychiatric diagnosis, the presence of a comorbid medical disorder, or a comorbid substance abuse disorder.

Psychiatric Referral

Referral for psychiatric consultation, treatment, and/or psychotherapy can occur at any time at the PCP’s discretion and/or the patient’s choice. In all cases, the mental health provider should communicate and coordinate with the PCP, after obtaining the patient’s permission.

It is strongly recommended that referral to the mental health provider be considered in any of the following circumstances:

- Significant evidence of danger to self or others
- Suspicion of Bipolar Disorder (note—Strongly consider psychiatric referral to any member who describes periods of (1) too much energy, and (2) lack of need for sleep. Use of antidepressant medications with bipolar members may further destabilize the clinical picture.)
- Presence of psychotic symptoms
- Treatment-resistant depression
- Depression during pregnancy and postpartum
- Childhood depression
- Depression with comorbid psychiatric/substance use disorders
- Depression with eating disorders
- Depression with Dementia
- Depression with severe/chronic medical disorder
Algorithm for Clinical Practice Guidelines for Depression in Adults in the Primary Care Setting

Diagram:

1. Diagnosis of clinical depression is made
   - Referral to a Behavioral Health Provider
   - Communication between PCP and Behavioral Health Provider
   - PCP initiates treatment with an antidepressant and encourages enrollment in a compliance enhancement program

2. Re-evaluate periodically during the first 12 weeks for side effects, positive response, and dosage adjustments

3. If partial or complete remission:
   - Continue treatment at same or adjusted dosage and re-evaluate periodically for side effects and continued positive response
   - If candidate for medication discontinuation at 12 months, D/C medication gradually and advise patient and family of early signs of recurrence

4. If unsatisfactory or no response:
   - Refer to a Behavioral Health Provider or switch antidepressants and repeat prior step
   - If patient is a candidate for indefinite antidepressant maintenance, continue antidepressant and re-evaluate every 3-6 months.

Patient Screening Tool

Patient Name: __________________________ Date: _____________

**Depression Screen**

Please answer each question by circling Yes or No.

During the past month, have you often been bothered by feeling down, sad, and hopeless?  
YES  NO

During the past month, have you noticed a decrease in your interest or pleasure in doing things?  
YES  NO

**Bipolar Screen**

Has there ever been a 4 day or longer period when you had racing thoughts, talked faster than usual, felt unusually good, and didn’t need your usual amount of sleep?  
YES  NO

Print this form as needed.
### Appendix 2  *(Adapted from PHQ – 9 (Nine Symptom Depression Checklist))*

#### Patient Questionnaire

Patient Name: __________________________ Date: _____________

**1. Over the last 2 weeks, how often have you experienced any of the following problems?**
   *(Place a ✓ in the response box)*

<table>
<thead>
<tr>
<th>Problem</th>
<th>Not at all</th>
<th>Several days</th>
<th>More than half the days</th>
<th>Nearly every day</th>
</tr>
</thead>
<tbody>
<tr>
<td>a. Little interest or pleasure in doing things</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>b. Feeling down, sad, or hopeless</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>c. Trouble falling asleep/staying asleep, sleeping too much</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>d. Feeling tired or having little energy</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>e. Poor appetite or overeating</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>f. Feeling bad about yourself - or that you are a failure or have let yourself or your family down</td>
<td></td>
<td></td>

Appendix 3

Patient Questionnaire Scoring Guideline

Appendix 1 – Patient Screening Tool
How to score Patient Screening Tool
This is a screening tool for both Major Depression and Bipolar Disorder. The first 2 screening questions relate to Major Depression and the 3rd question relates to Bipolar Disorder. A positive response to either screen does not confirm a diagnosis, rather a trigger for further evaluation. Strongly consider a psychiatric referral if the patient screens positive for Bipolar Disorder, since the diagnosis and treatment usually requires specialty oversight including the use of mood stabilizing agents and NOT antidepressants.

Appendix 2 – Patient Questionnaire
How to Score Patient Questionnaire
Major Depressive Syndrome is suggested if:

- Of the 9 items (a-i), 5 or more are checked as at least "More than half the days" and
- Either item a or b is positive, that is, at least "More than half the days"

Other Depressive Syndrome is suggested if:

- Of the 9 items (a-i), if b, c, or d are checked as at least "More than half the days" and
- Either item a or b is positive, that is, at least "More than half the days"

If depression is suspected, the score can be used to plan and monitor treatment. To score the questionnaire, tally each response by the number value under the answer headings:

- Not at all = 0
- Several days = 1
- More than half the days = 2
- Nearly every day = 3

Add the numbers together to total the score. Interpret the score by using the following guide.

Guide for Interpreting Patient Questionnaire Score
<table>
<thead>
<tr>
<th>Score</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>≤ 4</td>
<td>The score suggests the patient may not need depression treatment.</td>
</tr>
<tr>
<td>5 - 14</td>
<td>Physician uses clinical judgment about treatment, based on patient's duration of symptoms and functional impairment.</td>
</tr>
<tr>
<td>≥ 15</td>
<td>Warrants treatment for depression, use antidepressant, psychotherapy and/or a combination of treatment.</td>
</tr>
</tbody>
</table>

A functional health assessment is reflected in Question 2, which asks the patient how emotional difficulties or problems impact work, things at home, or relationships with other people. Patient responses can be one of four: not difficult at all, somewhat difficult, very difficult, or extremely difficult. A response of very difficult or extremely difficult suggests that the patient's functionality is impaired. After treatment begins, functional status is again measured to see if the patient is improving.
